Cancer therapy selection, dosing, administration, and the management of related adverse events can be a complex process that should be handled by an experienced healthcare team. Clinicians must choose and verify treatment options based on the individual patient; drug dose modifications and supportive care interventions should be administered accordingly. The cancer treatment regimens below may include both U.S. Food and Drug Administration-approved and unapproved indications/regimens. These regimens are only provided to supplement the latest treatment strategies.

These Guidelines are a work in progress that may be refined as often as new significant data becomes available. The NCCN Guidelines® are a consensus statement of its authors regarding their views of currently accepted approaches to treatment. Any clinician seeking to apply or consult any NCCN Guidelines® is expected to use independent medical judgment in the context of individual clinical circumstances to determine any patient’s care or treatment. The National Comprehensive Cancer Network makes no warranties of any kind whatsoever regarding their content, use, or application and disclaims any responsibility for their application or use in any way.

### Systemic Therapy for Waldenstrom Macroglobulinemia

**Note:** All recommendations are Category 2A unless otherwise indicated.

#### Primary Therapy—Non-Stem Cell Toxic

<table>

### Previously Treated WM/LPL—Stem Cell Transplant

<table>
<thead>
<tr>
<th>High-dose therapy with stem cell rescue</th>
<th>Treatment varied depending on local protocols.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allogeneic stem cell transplant</td>
<td>Preferably undertaken in the context of a clinical trial.</td>
</tr>
</tbody>
</table>

---

**a** In patients with symptomatic hyperviscosity, plasmapheresis should first be performed. Plasmapheresis should also be considered before treatment with rituximab or ofatumumab in patients with asymptomatic Waldenström’s macroglobulinemia and an IgM ≥4,000mg/dL to avoid aggravation of serum viscosity on the basis of rituximab-related IgM flare. Rituximab or ofatumumab may also be held in patients with elevated serum IgM levels for initial treatment cycles.

**b** Consider particularly for patients presenting with symptomatic hyperviscosity, or in whom rapid IgM reduction is required.

**c** Herpes zoster prophylaxis should be considered for patients receiving these regimens.

**d** These regimens are associated with treatment-related neuropathy and should be avoided in patients with disease-related neuropathy.

**e** Serial serum IgA and IgG levels should be carefully monitored as these patients can be depleted with carfilzomib therapy.

**f** Vincristine is associated with a high risk of peripheral neuropathy in patients with Waldenström’s macroglobulinemia/lymphoplasmacytic lymphoma. Consider alternative regimens without vincristine (eg, cyclophosphamide, dexamethasone, rituximab), if cyclophosphamide-based therapy is being considered.

**g** Lower overall responses and absence of major responses have been observed in patients with MYD88 wild-type mutations.

**h** May be associated with disease transformation and/or development of myelodysplastic syndrome / acute myeloid leukemia in patients with Waldenström’s macroglobulinemia.

**i** Avoid in patients who are potential autologous stem cell transplant candidates.

**j** Ofatumumab may be used for rituximab-intolerant individuals as a single agent or in combination therapy.

**k** Should ideally be undertaken in the context of a clinical trial.
